### Plan for today

#### More synchronization primitives

- Semaphore resource control, bounded buffer
- CyclicBarrier thread coordination
- Testing concurrent programs
  - BoundedQueue (FIFO) example
- Testing the test: Mutation
- Coverage and interleavings
  - Example: Deadlock, dining philosophers
  - Exploring interleavings with Java Pathfinder
- Concurrent correctness concepts

Based on slides by Peter Sestoft

## java.util.concurrent.Semaphore

- A semaphore holds zero or more permits
- void acquire()
  - Blocks till a permit is available, then decrements the permit count and returns
- void release()
  - Increments the permit count and returns; may cause another blocked thread to proceed
  - NB: a thread may call release() before acquire(), so a semaphore is different from a lock!
- A semaphore is used for resource control
  - Locking may be needed for data consistency

## A bounded queue using semaphores

```
class SemaphoreBoundedQueue <T> implements BoundedQueue<T> {
 private final Semaphore availableItems, availableSpaces;
 private final T[] items;
 private int tail = 0, head = 0;
 public SemaphoreBoundedQueue(int capacity) {
    this.availableItems = new Semaphore(0);
    this.availableSpaces = new Semaphore(capacity);
    this.items = makeArray(capacity);
 public void put(T item) throws InterruptedException { // tail
    availableSpaces.acquire();
                                         Wait for space
    doInsert(item);
    availableItems.release();
                                          Signal new item
 public T take() throws InterruptedException {
                                                         // head
    availableItems.acquire();
                                          Wait for item
    T item = doExtract();
    availableSpaces.release();
                                         Signal new space
    return item;
```

#### The doInsert and doExtract methods

```
class SemaphoreBoundedQueue <T> implements BoundedQueue<T> {
  private final Semaphore availableItems, availableSpaces;
  private final T[] items;
  private int tail = 0, head = 0;
  public void put(T item) throws InterruptedException { ... }
  public T take() throws InterruptedException { ... }
  private synchronized void doInsert(T item) {
    items[tail] = item;
    tail = (tail + 1) % items.length;
 private synchronized T doExtract() {
    T item = items[head];
    items[head] = null;
    head = (head + 1) % items.length;
    return item;
```

- Semaphores to block waiting for "resources"
- Locks (synchronized) for atomic state mutation

## **Bounded queue with capacity 2**

bounded queue(2) Thread A Thread B take() availableItems.acquire() put(7) availableSpaces.acquire() doInsert(7) availableItems.release() = doExtract() availableSpaces.release() put(9) availableSpaces.acquire() doInsert(9) availableItems.release() put(13) availableSpaces.acquire( doInsert(13) availableItems.release() put(17) **Blocked** availableSpaces.acquire()

### **Plan for today**

- More synchronization primitives
  - Semaphore resource control, bounded buffer
  - CyclicBarrier thread coordination
- Testing concurrent programs
  - BoundedQueue (FIFO) example
- Testing the test: Mutation
- Coverage and interleavings
  - Example: Deadlock, dining philosophers
  - Exploring interleavings with Java Pathfinder
- Concurrent correctness concepts

### **Testing BoundedQueue**

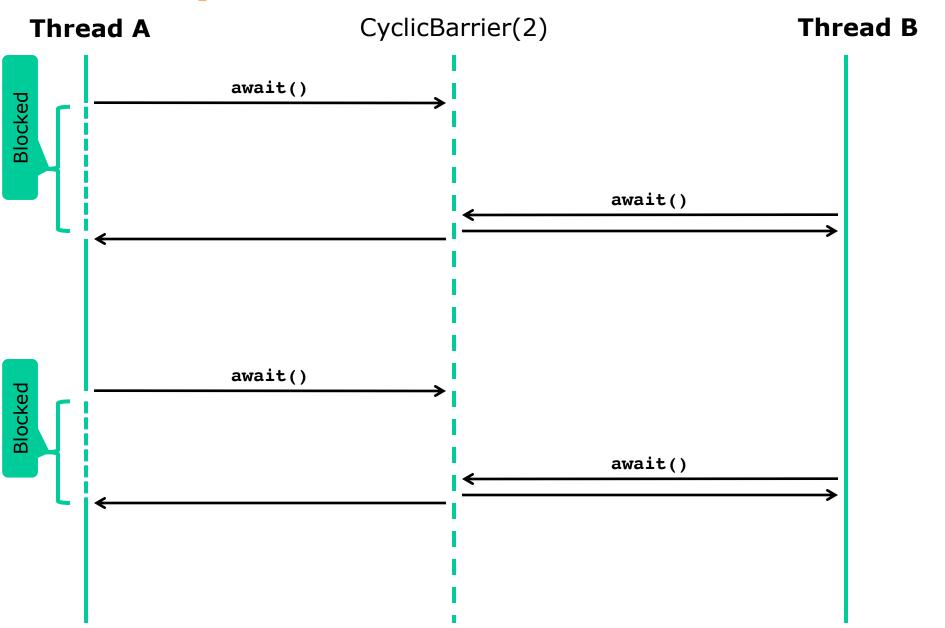

- Divide into
  - Sequential 1-thread test with *precise* results
  - Concurrent n-thread test with aggregate results
  - ... that make it *plausible* that invariants hold
- Sequential test for queue bq with capacity 3:

```
assertTrue(bq.isEmpty());
assertTrue(!bq.isFull());
bq.put(7); bq.put(9); bq.put(13);
assertTrue(!bq.isEmpty());
assertTrue(bq.isFull());
assertEquals(bq.take(), 7);
assertEquals(bq.take(), 9);
assertEquals(bq.take(), 13);
assertTrue(bq.isEmpty());
assertTrue(!bq.isFull());
```

## java.util.concurrent.CyclicBarrier

- A CyclicBarrier(N) allows N threads
  - to wait for each other, and
  - proceed at the same time when all are ready
- int await()
  - blocks until all N threads have called await
  - may throw InterruptedException
- Useful to start n test threads + 1 main thread at the same time, N = n + 1
- Writes before await is called are visible after it returns, in all threads passing the barrier

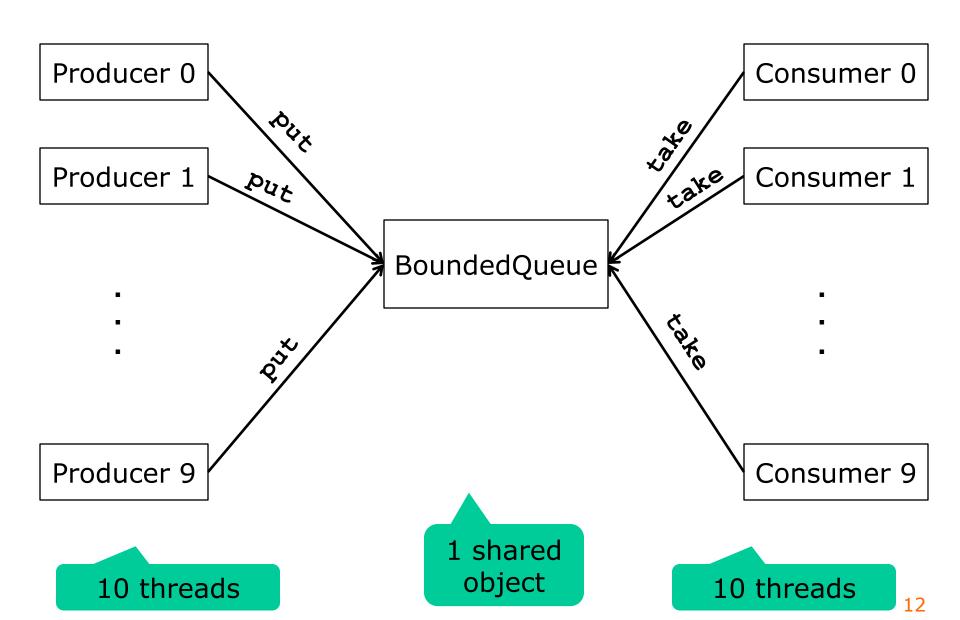

## **Cyclic barrier with count 2**

#### **Concurrent test of BoundedQueue**

- Run 10 producer and 10 consumer threads
  - Each producer inserts 100,000 random numbers
    - Using a thread-local random number generator
  - Each consumer extracts 100,000 numbers
- Afterwards, check that
  - All consumers terminate, do not block on empty
  - The bounded queue is again empty
  - The sum of consumed numbers equals the sum of produced numbers
- Producers and consumers must sum numbers
  - Using a thread-local sum variable, and afterwards adding to a common AtomicInteger

#### **Concurrent test of BoundedQueue**

#### The PutTakeTest class

```
Initialize to 2*nPairs+1
class PutTakeTest extends Tests {
 protected CyclicBarrier startBarrier, stopBarrier;
 protected final BoundedQueue<Integer> bq;
                                                        Being tested!
 protected final int nTrials, nPairs;
 protected final AtomicInteger putSum = new AtomicInteger(0);
 protected final AtomicInteger takeSum = new AtomicInteger(0);
 void test(ExecutorService pool) {
    try {
      for (int i = 0; i < nPairs; i++)
                                             Make nPairs Producers
       pool.execute(new Producer());
                                             and nPairs Consumers
       pool.execute(new Consumer());
      startBarrier.await(); // wait for all threads to be ready
      stopBarrier.await(); // wait for all threads to finish
      assertTrue(bq.isEmpty());
                                                             Main: start,
      assertEquals(putSum.get(), takeSum.get());
                                                            finish threads
    } catch (Exception e) {
      throw new RuntimeException(e);
                                        Check that total
                                       effect is plausible
```

#### A Producer test thread

```
class Producer implements Runnable {
                                                                         256
 public void run() {
   try {
                                             Thread-local Random
     Random random = new Random();
      int sum = 0;
                                              Wait till all are ready
      startBarrier.await();
      for (int i = nTrials; i > 0; --i)
        int item = random.nextInt();
                                             Put 100,000 numbers
       bq.put(item);
        sum += item;
                                             Add to global putSum
      putSum.getAndAdd(sum);
      stopBarrier.await();
                                               Signal I'm finished
    } catch (Exception e) {
      throw new RuntimeException(e);
```

#### A Consumer test thread

```
class Consumer implements Runnable {
                                                                          256
 public void run() {
   try {
                                              Wait till all are ready
      startBarrier.await();
      int sum = 0;
      for (int i = nTrials; i > 0;
                                             Take 100,000 numbers
        sum += bq.take();
                                             Add to global takeSum
      takeSum.getAndAdd(sum);
      stopBarrier.await();
                                               Signal I'm finished
    } catch (Exception e) {
      throw new RuntimeException(e);
```

#### Reflection on the concurrent test

- Checks that item count and item sum are OK
- The sums say nothing about item order
  - Concurrent test would be satisfied by a stack also
  - But the sequential test would not
- Could we check better for item order?
  - Could use 1 producer, put'ting in increasing order;
     and 1 consumer take'ing and checking the order
    - But a queue correct for 1 producer and 1 consumer may be incorrect for multiple producers or multiple consumers
  - Could make test synchronize between producers and consumers, but
    - Reduces test thread interleaving and thus test efficacy
    - Risk of artificial deadlock because queue synchronizes also

#### **Techniques and hints**

- Create a local random number generator for each thread, or use ThreadLocalRandom
  - Else may limit concurrency, reduce test efficacy
- Do no synchronization between threads
  - May limit concurrency, reduce test efficacy
- Use CyclicBarrier(n+1) to start n threads
  - More likely to run at the same time, better testing
- Use it also to wait for the threads to finish
  - So main thread can check the results
- Test on a *multicore* machine, 4-16 cores
- Use more test threads than cores
  - So some threads occasionally get de-scheduled

### **Plan for today**

- More synchronization primitives
  - Semaphore resource control, bounded buffer
  - CyclicBarrier thread coordination
- Testing concurrent programs
  - BoundedQueue (FIFO) example
- Testing the test: Mutation
- Coverage and interleavings
  - Example: Deadlock, dining philosophers
  - Exploring interleavings with Java Pathfinder
- Concurrent correctness concepts

## How good is that test? Mutation testing and fault injection

- If some code passes a test,
  - is that because the code is correct?
  - or because the test is too weak: bad coverage?
- To find out, mutate the program, inject faults
  - eg. remove synchronization
  - eg. lock on the wrong object
  - do anything that should make the code not work

- If it still passes the test, the test is too weak
  - Improve the test so it finds the code fault

### **Mutation testing quotes**

a program P which is correct on test data T is subjected to a series of mutant operators to produce mutant programs which differ from P in very simple ways. The mutants are then executed on T. If all mutants give incorrect results then it is very likely that P is correct (i.e., T is adequate).

On the other hand, if some mutants are correct on T then either: (1) the mutants are equivalent to P, or (2) the test data T is inadequate. In the latter case, T must be augmented by examining the non-equivalent mutants which are correct on T:

Budd, Lipton, Sayward, DeMillo: The design of a prototype mutation system for software testing, 1978

## Some mutations to BoundedQueue

```
public void put(T item) throws InterruptedException { // tail
  availableSpaces.acquire();
                                                   Insert
                                 Delete
  doInsert(item);
  availableItems.release();
                               availableSpaces.release()
                          Delete
private synchronized void doInsert(T item) {
  items[tail] = item;
  tail = (tail + 1) % items.length;
                          Delete
private synchronized T doExtract() {
    T item = items[head];
                                Delete
    items[head] = null;
    head = (head + 1) % items.length;
    return item;
  }
                     Delete
```

### Plan for today

- More synchronization primitives
  - Semaphore resource control, bounded buffer
  - CyclicBarrier thread coordination
- Testing concurrent programs
  - BoundedQueue (FIFO) example
- Testing the test: Mutation
- Coverage and interleavings
  - Example: Deadlock, dining philosophers
  - Exploring interleavings with Java Pathfinder
- Concurrent correctness concepts

#### **Test coverage**

#### Sequential

- Method coverage: has each method been called?
- Statement coverage: has each statement been executed?
- Branch coverage: have all branches of if, for, while, do-while, switch, try-catch been executed?
- Path coverage: have all paths through the code been executed? (very unlikely)

#### Concurrent

 Interleaving coverage: have all interleavings of different methods' execution paths been tried? (extremely unlikely)

## Thread interleavings

Two threads both doing count = count + 1:

Thread A: read count; add 1; write count

Thread B: read count; add 1; write count

read count add 1 write count read count add 1 write count

read count add 1 read count write count add 1 write count

read count add 1 read count add 1 write count write count read count add 1 read count add 1 write count write count

read count read count add 1 write count add 1 write count

read count read count add 1 add 1 write count write count read count read count add 1 write count add 1 write count read count read count add 1 add 1 write count write count

read count read count add 1 add 1 write count write count read count read count add 1 add 1 write count write count

Plus 10 symmetric cases, swapping red and blue

## Thread interleaving for testing

- To find concurrency bugs, we want to exercise all interesting thread interleavings
- How many: N threads each with M instructions have (NM)!/(M!)<sup>N</sup> possible interleavings
  - Zillions of test runs needed to cover interleavings
- PutTakeTest explores at most 1m of them
  - And JVM may be too deterministic and explore less
- One can increase interleavings using
   Thread.yield() or Thread.sleep(1)
  - But this requires modification of the tested code
  - Or special tools: Java Pathfinder, Microsoft CHESS

## How large is (NM)!/(M!)<sup>N</sup> in reality?

```
def fac(n: Int): BigInt = if (n==0) 1 else n*fac(n-1)

def power(M: BigInt, P: Int): BigInt = if (P == 0) 1 else M*power(M, P-1)

def interleaving(N : Int, M : Int) = fac(N*M) / power(fac(M), N)
```

```
interleaving(1, 15) is 1
interleaving(5, 1) is 120
interleaving(5, 2) is 113400
interleaving(2, 3) is 20
```

interleaving(5, 3) is 168168000

Number of ways to interleave N threads each having M instructions

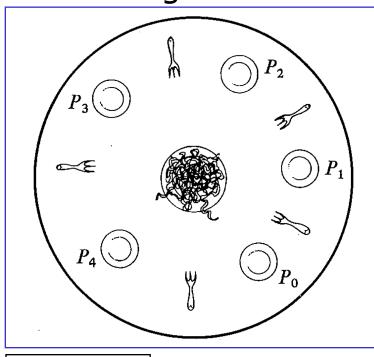

```
interleaving(5, 100) is
17234165594777008534148379284721996814952838615864289522194894697

34826943434743360000$
```

#### The Java Pathfinder tool

- NASA project at http://babelfish.arc.nasa.gov/trac/jpf
- A Java Virtual Machine that
  - can explore all computation paths
  - supervise the execution with "listeners"
  - generate test cases
- Properties of Java Pathfinder
  - a multifaceted research project
  - slow execution of code
  - much better test coverage, eg deadlock detection
  - works for Java 7, some of Java 8, so far

#### **Deadlock**

- A deadlock occurs when threads are forever blocked waiting to take a lock
- Example: Dining philosophers (Dijkstra 1965)
  - A philosopher P<sub>i</sub> eats or thinks
  - To eat (spaghetti), he needs left and right forks
- Deadlock risk scenario
  - Each P<sub>i</sub> takes left fork
  - Forever waits for right fork
- Depends on interleaving of threads' activities

```
class Philosopher implements Runnable {
 private final Fork[] forks;
 private final int place;
 public void run() {
    while (true) {
      int left = place, right = (place+1) % forks.length;
      synchronized (forks[left]) {
                                                    Exclusive
        synchronized (forks[right]) {
                                                   use of forks
          System.out.print(place + " "); // Eat
      try { Thread.sleep(10); }
                                          // Think
      catch (InterruptedException exn) { }
```

Bad

```
Fork[] forks = { new Fork(), new Fork(), new Fork(), new Fork(), new Fork() };
for (int place=0; place<forks.length; place++) {
   Thread phil = new Thread(new Philosopher(forks, place));
   phil.start();
}</pre>

5 forks shared by
5 philosopher threads
}
```

#### Java Pathfinder example

- TestPhilosophers on 1 core never deadlocks
  - at least not within the bounds of my patience ...
- But Java Pathfinder discovers a deadlock
  - because it explores many thread interleavings

#### Aside: How to avoid deadlock

- In theory, easy to avoid deadlock
  - Define a total ordering for the locks
  - Make all threads take the locks in that order
- For example, dining philosophers
  - Number the forks 0...4
  - A philosopher takes two forks in numeric order
  - So  $P_0$  takes  $F_0$   $F_1$ ;  $P_1$  takes  $F_1$   $F_2$ ; ...;  $P_4$  takes  $F_0$   $F_4$
- In practice, difficult to avoid deadlock
  - Lock order must involve all locks in the program
  - So not compositional: even if two subprograms are deadlock-free, together they may not be
  - Transactional memory (next week) is a solution

## Deadlock-freedining philosophers

```
class Philosopher implements Runnable {
 private final Fork[] forks;
 private final int place;
 public void run() {
                           Implementing the solution of
   while (true) {
                           the previous slide
      int first, second;
      if (place <= 3) {
         first = place;
         second = (place + 1) % forks.length;
       } else {
         first = (place + 1) % forks.length;
         second = place;
      synchronized (forks[first]) {
        synchronized (forks[second]) {
          System.out.print(place + " "); // Eat
      }
      try { Thread.sleep(10); }
                                          // Think
      catch (InterruptedException exn) { }
    } } }
```

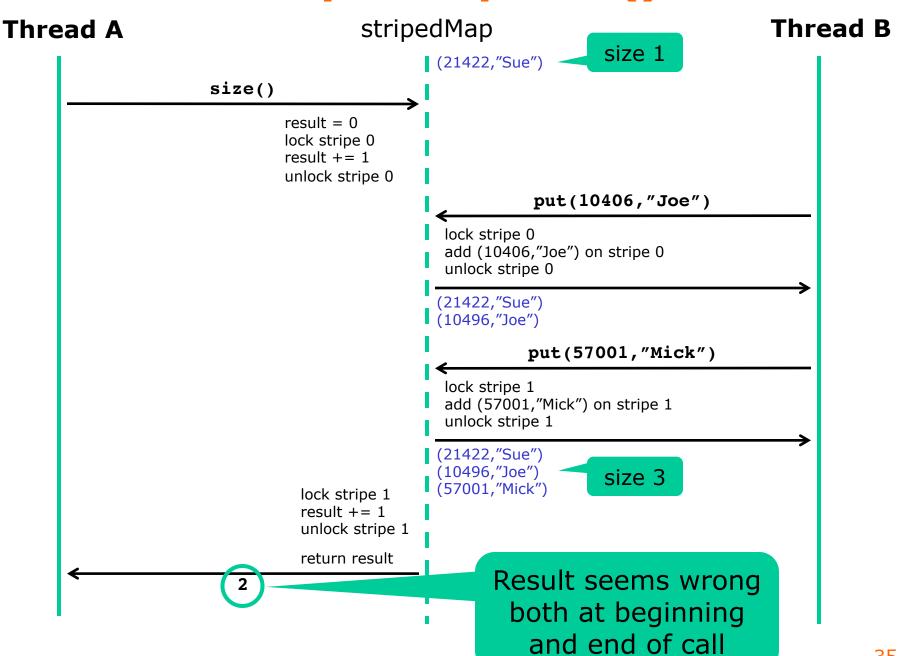

#### Plan for today

- More synchronization primitives
  - Semaphore resource control, bounded buffer
  - CyclicBarrier thread coordination
- Testing concurrent programs
  - BoundedQueue (FIFO) example
- Testing the test: Mutation
- Coverage and interleavings
  - Example: Deadlock, dining philosophers
  - Exploring interleavings with Java Pathfinder
- Concurrent correctness concepts

#### **Correctness concepts**

- Quiescent consistency
  - Method calls separated by a period of quiescence should appear to take effect in their real-time order
  - Says nothing about overlapping method calls
- Sequential consistency
  - Method calls should appear to take effect in program order – seen from each thread
- Linearizability
  - A method call should appear to take effect at some point between its invocation and return
  - This is called its linearization point

#### When is StripedMap.size() correct?

## **Quiescent consistency**

- Principle 3.3.2: Method calls separated by a period of quiescence should appear to take effect in their real-time order
  - This says nothing about overlapping method calls
  - This assumes we can observe inter-thread actions

#### Java's ConcurrentHashMap:

"Bear in mind that the results of aggregate status methods including size, isEmpty, and containsValue are typically useful only when a map is not undergoing concurrent updates in other threads.

Otherwise the results of these methods reflect transient states that may be adequate for monitoring or estimation purposes, but not for program control."

# Queue example code

```
class LockBasedQueue<T> {
 private final T[] items;
                    int tail = 0, head = 0;
 private
 public synchronized boolean eng(T item) {
   if (tail - head == items.length)
      return false:
    else {
      items[tail % items.length] = item;
      tail++;
      return true;
                                                             Cannot
                                                             overlap
 public synchronized T deq() {
    if (tail == head)
      return null;
    else {
      T item = items[head % items.length];
     head++;
      return item;
```

- With locking, state changes cannot overlap
  - Method call "takes effect" when releasing the lock, at return

### Restricted-use queue without locks

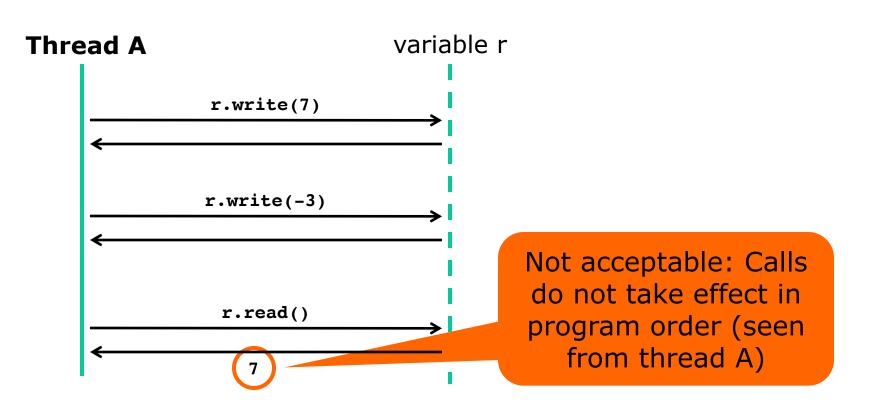

```
class WaitFreeOueue<T> {
 private final T[] items;
 private volatile int tail = 0, head = 0;
                      boolean eng(T item) {
 public
    if (tail - head == items.length)
      return false;
    else {
      items[tail % items.length] = item;
     tail++;
      return true;
 public
                      T deq() {
    if (tail == head)
      return null;
    else {
      T item = items[head % items.length];
     head++;
      return item;
 } } }
```

- Correct if there is only one enqueuer and one dequeuer
- Even if concurrent!
- Only enq writes tail
- Only deq writes head
- enq and deq never write same items[i]
- Visibility ensured by volatile
- Subtle ...

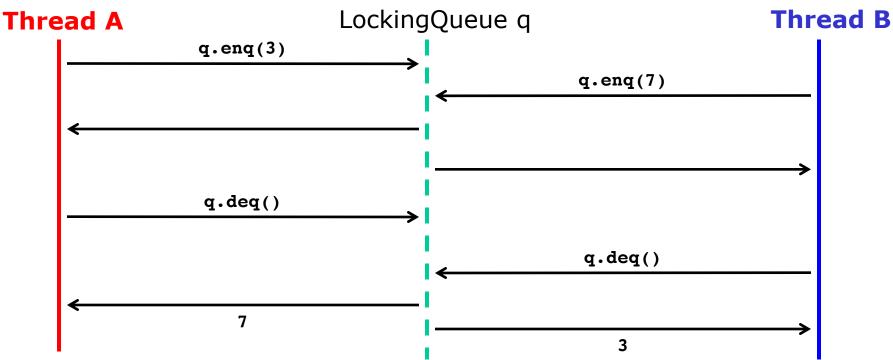

- No locking, so state updates may overlap!
  - One thread calling enq, another calling deq
  - Now what would it mean for WaitFreeQueue to be "correct"?

## Sequential consistency

- Principle 3.4.1: Method calls should appear to take effect in program order
  - Program order is the order within a single thread
- The full execution is an interleaving of each thread's executions

52

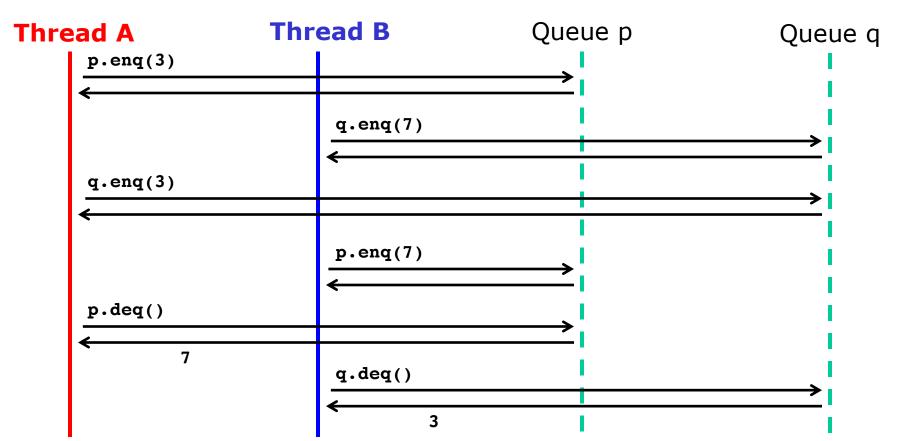

Two "global" scenarios showing seq cons:

A q.enq(3)Bq.enq(7)B q.deq(3)A q.deq(7)

Bq.enq(7)A q.enq(3)A q.deq(7)Bq.deq(3)

# Separately not jointly seq. cons.

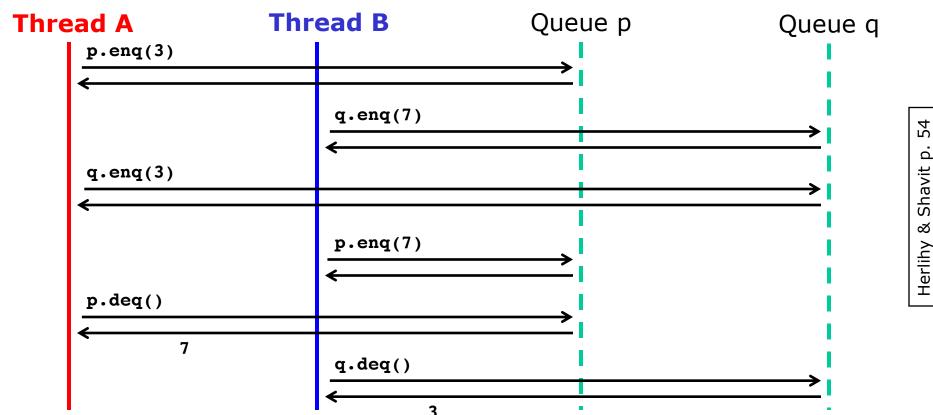

Sequentially consistent for each queue p, q:

B p.enq(7)A p.enq(3) | AND | A p.deq(7)

A q.enq(3)B q.enq(7)Bq.deq(3)

BUT assume different orders of p.enq(7) and p.enq(3)

# Cannot be jointly seq. consistent

- p.enq(7) must precede p.enq(3) because dequeues 7
  - which precedes q.enq(3) in thread A program order
- q.enq(3) must precede q.enq(7) because dequeues 3
  - which precedes p.enq(7) in thread B program order
- So p.enq(7) must precede p.enq(7), impossible

Shavit

## Reflection on sequential consistency

- Seems a natural expectation
- It is what synchronization tries to achieve
- If all (unsynchronized) code were to satisfy it, that would preclude optimizations:

Java (and C#) does not guarantee sequential consistency of accesses to non-synchronized non-volatile fields (eg. JLS § 17.4.3)

- The lack of compositionality makes sequential consistency a poor reasoning tool
  - Using a bunch of sequentially consistent data structures together does not give seq. consistency

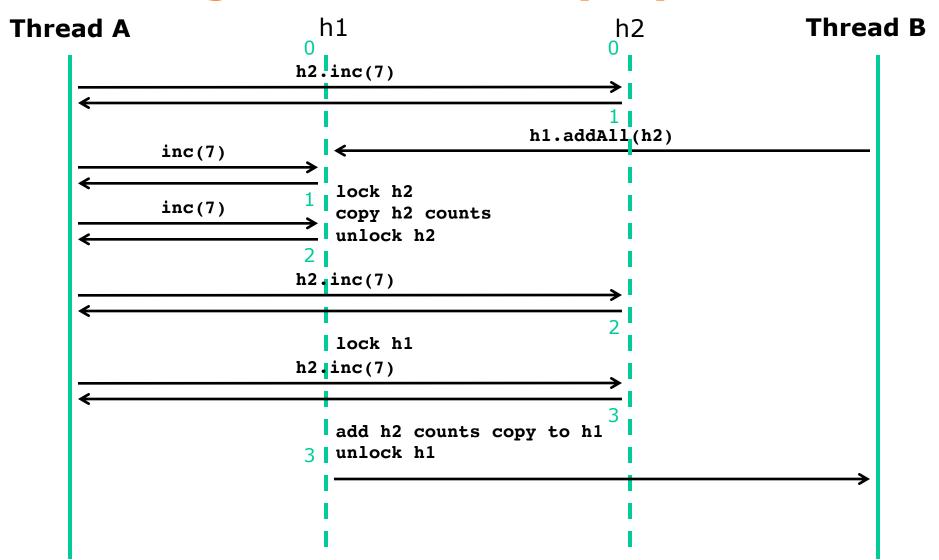

### Linearizability

- Principle 3.5.1: Each method call should appear to take effect instantaneously at some moment between its invocation and response.
- Usually shown by identifying a linearization point for each method.
- In Java monitor pattern methods, the linearization point is usually at lock release
- In non-locking WaitFreeQueue<T>
  - linearization point of enq() is at tail++ update
  - linearization point of deq() is at head++ update
- Less clear in lock-free methods, week 10-11

# Restricted-use queue without locks

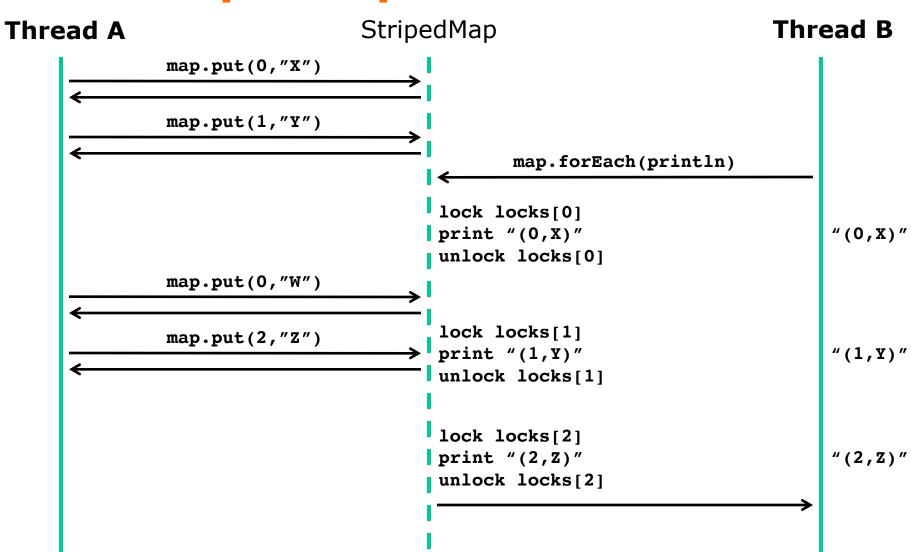

```
class WaitFreeQueue<T> {
                                                NB: Only one
 private final T[] items;
                                                 enqueuer and one
 private volatile int tail = 0, head = 0;
                                                 dequeuer thread!
 public
                      boolean enq(T item) {
    if (tail - head == items.length)
      return false;
   else {
      items[tail % items.length] = item;
     tail++;
                                            Linearization
     return true;
                                                point
 public
                      T deq() {
    if (tail == head)
     return null;
   else {
     T item = items[head % items.length];
     head++;
                                            Linearization
     return item;
                                                point
} } }
```

# A Histogram h1.addAll(h2) scenario

The result does not reflect the joint state of h1 and h2 at any point in time. (Because h1 may be updated while h2 is locked, and vice versa).

### A StripedMap.forEach scenario

Seen from Thread A it is strange that (2,Z) is in the map but not (0,W). (Stripe 0 is enumerated before stripe 2, and stripe 1 updated in between).

### **Concurrent bulk operations**

These typically have rather vague semantics:

"Iterators and Spliterators provide weakly consistent [...] traversal:

- they may proceed concurrently with other operations
- •...
- •they are guaranteed to traverse elements as they existed upon construction exactly once, and may (but are not guaranteed to) reflect any modifications subsequent to construction"

Package java.util.concurrent documentation

- The three bullets hold for StripedMap.forEach
- Precise test only in quiescent conditions
  - But (a) it does not skip entries that existed at call time, and (b) it does not process any entry twice

#### This week

- Reading
  - Goetz et al chapter 12
  - Herlihy & Shavit chapter 3 (PDF on LearnIT)
- Exercises
  - Show you can test concurrent software with subtle synchronization mechanisms
- Read before next week's lecture
  - Herlihy and Shavit sections 18.1-18.2 (LearnIT)
  - Harris et al: Composable memory transactions
  - Cascaval et al: STM, Why is it only a research toy
